Abstract

This study reports a Czech adaptation of the Hartmann and Hasselhorn Historical Perspective Taking (HPT) instrument and examines whether its politically charged scenario introduces construct-irrelevant variance (CIV) related to students' ideological attitudes. Among 293 Czech secondary students, confirmatory factor analysis favored a correlated three-factor representation. An item-level bias analysis detected no differential item functioning across ideology groups with this sample and procedure. Multi-group factor analysis produced fit-index changes compatible with scalar invariance, but small extreme groups and unmodelled clustering limit the strength of that evidence. Historical knowledge correlated with the primary six-item contextualization composite ($r = .34$,

95% CI [.23, .43]); the combined ideology score was unrelated ($r = -.05$, 95% CI [−.16, .07]). These findings support a possible protocol for evaluating measurement fairness when assessment content carries attitudinal valence, subject to the limits of this single scenario, item format, and ideologically restricted sample.

Keywords: historical perspective taking, cross-cultural validation, measurement invariance, differential item functioning, construct-irrelevant variance, test fairness

1. Introduction

Cross-cultural adaptation of educational and psychological instruments requires more than linguistic translation: it demands evidence that the adapted version measures the same construct, with equivalent psychometric properties, in the target population (American Educational Research Association, American Psychological Association, & National Council on Measurement in Education, 2014; Hambleton, Merenda, & Spielberger, 2005; International Test Commission, 2017). When assessment content carries attitudinal valence—when scenarios, stimuli, or items touch on beliefs that respondents may hold—an additional fairness question arises: does the content introduce construct-irrelevant variance (CIV) by functioning differently for subgroups whose attitudes align with that content (Messick, 1995)? This question is especially pressing for scenario-based instruments in the social sciences, where rich contextual material is needed to elicit complex reasoning but may simultaneously activate respondents' pre-existing attitudes. Historical perspective taking (HPT)—the capacity to reconstruct the beliefs, values, and circumstances that made past actors' decisions intelligible in their own time (Hartmann

& Hasselhorn, 2008; Lee & Ashby, 2001)—provides a particularly informative case. HPT instruments routinely use politically and morally charged historical scenarios as the stimulus for disciplinary reasoning (reasoning according to the methodological norms of the historical discipline, such as source criticism and contextualization; van Drie & van Boxtel, 2008; Seixas & Morton, 2013; Wineburg, 2001).

The instrument reported by Hartmann and Hasselhorn (2008) provides a scenario-based measure of HPT. It was validated with German Grade 10 students (Hartmann & Hasselhorn, 2008) and subsequently translated and studied with Dutch students aged 10–17 (Huijgen, van Boxtel, van de Grift, & Holthuis, 2014, 2017). This evidence base is promising but remains concentrated in two language contexts and a small number of studies. The instrument operationalizes HPT through a scenario-based approach in which students read about a historically situated dilemma and respond to nine Likert-scaled items in three interpretive response categories: present-oriented perspective (POP), role of the historical agent (ROA), and historical contextualization (CONT). POP and CONT represent the clearest contrast between present-centered judgment and contextual reasoning; ROA's position as an intermediate level remains theoretically less certain (Hartmann & Hasselhorn, 2008; Lee & Ashby, 2001).

The present study reports a Czech adaptation and psychometric evaluation of the Hartmann and Hasselhorn HPT instrument. Two considerations motivate this work. First, no validated Czech-language HPT instrument was identified. Czech initiatives have developed digital historical-literacy tasks and measures of epistemic beliefs about history (Ripka, Sýkorová, Münich, & Chvojka, 2024; Činátl, Najbert, & Ripka, 2021); the present

adaptation provides a candidate instrument for further Czech validation and future cross-national equivalence studies.

Second, the instrument's scenario content raises a specific fairness question. Hannes discusses Germany's crisis and the 1930 election; students judge how well nine explanations fit his situation, including whether he could vote for an anti-democratic party such as the NSDAP. These judgments could, in principle, function differently for students whose political attitudes align with the scenario's ideological content. Students with right-authoritarian sympathies might find it cognitively easier to endorse contextualizing responses—not because they are reasoning historically, but because the responses resonate with their own attitudes. If present, such a pattern would constitute construct-irrelevant variance (CIV): systematic score variation attributable to a factor extraneous to the target construct (American Educational Research Association et al., 2014; Messick, 1995).

This concern is not merely theoretical. Research on identity-protective cognition demonstrates that individuals process information through the lens of pre-existing beliefs (Jost, Glaser, Kruglanski, & Sulloway, 2003; Kahan, Peters, Dawson, & Slovic, 2017). Recent work has documented how ideological content can infiltrate competence judgments in history assessment, whether through teacher scoring bias in open-ended narrative assessment (Alvén, 2019) or through construct comparability challenges in cross-cultural settings (Badham, Meadows, & Baird, 2025). The question central to the present study is whether the HPT instrument's psychometric properties—its factor structure, item parameters, and score interpretations—hold equivalently across students with different political

attitudes, or whether politically charged content introduces measurement bias.

The study contributes to the literature in three ways: (a) it applies a possible methodological approach for evaluating whether attitudinally charged assessment content introduces construct-irrelevant variance, (b) it provides DIF and measurement-invariance evidence across political-ideology groups, and (c) it adds Czech evidence to the small cross-cultural evidence base for this measure. To establish this evidence, we conducted confirmatory factor analysis (CFA), reliability analysis, intraclass correlation estimation, IRT-based differential item functioning (DIF) analysis, and multi-group CFA for measurement invariance testing.

2. Literature Review

2.1 Historical Perspective Taking and Its Measurement

HPT refers to the ability to understand past actors' decisions by reconstructing the historical context in which they operated (Hartmann & Hasselhorn, 2008; Lee & Ashby, 2001). HPT is a second-order (procedural or disciplinary) concept—as distinct from first-order (substantive) concepts such as “revolution” or “empire,” it concerns the meta-level reasoning processes historians use to make sense of the past (Seixas & Peck, 2004). The concept has roots in British traditions that progressively refined the construct from historical empathy (*Children's concepts of empathy and understanding in history*, 1987; Shemilt, 1984) toward rational reconstruction (Lee & Ashby, 2001). It has been situated within broader frameworks of historical reasoning that encompass evidence use, argumentation, and substantive concept deployment—the application of domain-specific content knowl-

edge about events, causes, and actors (van Boxtel & van Drie, 2018; van Drie & van Boxtel, 2008; VanSledright, 2014). The literature variously labels this capacity “historical empathy,” “perspective taking,” or “rational reconstruction.” We follow Hartmann and Hasselhorn (2008) in adopting the term “perspective taking” within the rationalist tradition of Lee and Ashby (2001), which emphasizes cognitive reconstruction of context rather than affective identification with past actors (see Barton & Levstik, 2004, for a contrasting view that emphasises affective engagement alongside cognitive reconstruction; see also Endacott, 2014; Endacott & Brooks, 2013, for treatments of the empathy/perspective-taking distinction). The present instrument therefore operationalises cognitive perspective taking, not the fuller cognitive-affective construct of historical empathy. Across these frameworks, HPT is understood as a cognitively demanding, knowledge-dependent competence—not a disposition but a disciplinary achievement requiring both domain-specific knowledge and the capacity to deploy that knowledge in reconstructing past perspectives (Chapman, 2021; VanSledright, 2014; Wineburg, 2001). Distinguishing genuine disciplinary reasoning from attitude-driven responding is a measurement challenge that extends beyond HPT to epistemic cognition in history more broadly (Maggioni, VanSledright, & Alexander, 2009). Hartmann and Hasselhorn (2008) operationalized HPT using three response categories: *present-oriented perspective* (POP), where students judge historical actors by contemporary standards; *role of the historical agent* (ROA), where students explain action through familiar or stereotyped social roles; and *contextualization* (CONT), where students situate decisions within the specific historical conditions that rendered them intelligible. The POP–CONT continuum from present-centered judgment toward contextualization has empirical paral-

127 lels in earlier work on students' historical understanding (Lee & Shemilt, 2003). The origi-
128 nal published validation study ($n = 170$ German students, Grade 10; Hartmann & Hassel-
129 horn, 2008) placed raw POP and CONT at opposing poles of one principal component and
130 ROA on a second, less clearly interpreted component (explained variance = 51%); a sepa-
131 rate latent-class analysis identified three student classes. Students classified in the highest
132 class had significantly better history grades; however, PCA is an exploratory technique,
133 and the present study tests a correlated three-factor representation rather than reproduc-
134 ing the original PCA dimensions. Huijgen et al. (2014) replicated the two-dimensional
135 pattern for the Nazi-party scenario with Dutch students, but transfer of the item-rating ap-
136 proach to a slavery scenario produced weaker reliability and validity evidence. Huijgen
137 et al. (2017) subsequently combined the closed item ratings with think-alouds and doc-
138 umented how students interpreted and sometimes misunderstood the response options.
139 Thus, successful reuse of the Nazi scenario does not establish that the format transfers
140 unchanged across topics or elicits the intended process.

141 The difficulty of measuring HPT stems from its inherently interpretive character. Un-
142 like factual recall, HPT cannot be adequately inferred from decontextualized factual-recall
143 items alone (Breakstone, 2014; Smith, 2017). Scenario-based instruments address this chal-
144 lenge by presenting contextual information and requiring students to evaluate statements
145 reflecting different levels of historical reasoning (Hartmann & Hasselhorn, 2008; Seixas,
146 Gibson, & Ercikan, 2015). However, this approach introduces a measurement tension:
147 the richer the historical context, the more opportunity for construct-irrelevant factors—
148 including attitudes toward that content—to influence responses.

2.2 Cross-Cultural Test Adaptation

The adaptation of educational and psychological instruments across languages and cultures requires systematic procedures to ensure that the adapted version measures the same construct as the original (Hambleton et al., 2005; International Test Commission, 2017). The International Test Commission (ITC) guidelines emphasize that adaptation involves more than translation: it requires attention to construct equivalence, cultural appropriateness, and technical quality of the adapted version (International Test Commission, 2017). For instruments used in history education, cross-cultural adaptation faces the additional challenge that historical content may carry different resonances across national contexts. A scenario about the Weimar Republic, originally designed for German students, intersects differently with Czech historical memory—while subsequent events shape contemporary Czech memory of the interwar period, the scenario centres on Weimar-era de-liberation (early 1930s), which predates the 1938 Munich Agreement and cession of the Sudetenland by approximately eight years. Nevertheless, the broader period connects directly to the Nazi occupation of 1939–1945 in Czech collective memory.

In Czech lower-secondary education, history is prescribed within the compulsory People and Society curriculum area for Grades 6–9. The framework includes the 1920s and 1930s, fascism, Nazism, totalitarianism, and work with historical sources, but does not define HPT as a separate competence (Ministerstvo školství, mládeže a tělovýchovy, 2023, pp. 54–58, 140, 143). School curricula broadly align with this framework, although curriculum documents describe intended rather than enacted provision (Kaleta, 2025). Participating teachers reported that students had encountered the relevant interwar content; this does

not establish equivalent prior instruction across schools.

This documentary account applies specifically to the lower-secondary subsample. The majority of participants were enrolled in upper-secondary education, for which this study did not conduct an equivalent curriculum- document audit. Eligibility at both levels required teacher confirmation that students had completed the interwar unit, but that confirmation is not evidence of uniform curricular coverage or instruction.

Cross-cultural validation studies should demonstrate that the adapted instrument preserves the factor structure, reliability, and validity relationships of the original (Hambleton et al., 2005). At minimum, this requires confirming the theorized factor structure through CFA, reporting reliability estimates appropriate for the item characteristics, and providing convergent validity evidence through expected correlations with related constructs. When the instrument will be used to compare groups or predict outcomes, measurement invariance testing becomes essential (American Educational Research Association et al., 2014).

2.3 Construct-Irrelevant Variance in Educational Assessment

The unified validity framework identifies construct-irrelevant variance as a principal threat to score interpretation (American Educational Research Association et al., 2014; Messick, 1995). CIV occurs when systematic variance in test scores is attributable to factors extraneous to the target construct. When assessment content intersects with respondents' attitudes or social identities, CIV can arise through attitude-consistent responding: students whose beliefs align with test content may find certain response

options more natural or appealing, inflating their scores without corresponding gains in the assessed competence (Messick, 1995).

For the HPT instrument specifically, the concern is that the Weimar Republic scenario creates a *congruence pathway*—a mechanism whereby attitudinal similarity to item content lowers the cognitive effort required to endorse a response, inflating scores independently of competence. Consider a contextualization item such as “His decision was understandable given the political and economic turmoil of the Weimar Republic.” A student who endorses this statement because she has reconstructed the historical context produces a valid HPT response. But a student who endorses it because the sentiment resonates with her own political sympathies—not because she has engaged in historical reasoning—produces an inflated score. This would represent construct contamination in Messick’s (1995) terms—a systematic source of score variance unrelated to HPT competence. Evidence of internal structure, including measurement invariance across relevant subgroups, constitutes essential validity evidence when scores are used to compare groups or when the construct definition requires demonstrating that extraneous factors do not influence scores (American Educational Research Association et al., 2014).

An alternative theoretical prediction deserves mention. Research on authoritarian cognition suggests that high authoritarianism is associated with reduced integrative complexity—the cognitive capacity to hold and reconcile multiple conflicting perspectives simultaneously (Duckitt, 2001; Suedfeld & Tetlock, 1977). Because HPT requires precisely this kind of integrative capacity, authoritarian students might perform *worse*, not better. The direction of any bias, if present, was genuinely uncertain. Additionally,

dual-process theories of cognition (Evans & Stanovich, 2013) suggest that structured assessment formats may channel deliberative processing, overriding the automatic attitude-retrieval processes that would produce attitude-consistent responding. If so, the assessment format itself may buffer against attitudinal interference.

The construct boundary is therefore consequential. Under broader accounts of historical empathy, affective engagement and morally responsive evaluation can be target-relevant aspects of understanding a past actor (Barton & Levstik, 2004; Endacott & Brooks, 2013). Under the narrower cognitive definition operationalized here, target variance consists of reconstructing context and integrating historically relevant considerations. Moral reaction or affect is not itself scored, and endorsement driven by option familiarity, task demands, or attitude congruence is construct-irrelevant when it substitutes for that reconstruction. The rating data alone cannot determine which process produced an endorsement.

2.4 DIF and Measurement Invariance as Fairness Evidence

Differential item functioning and measurement invariance testing provide complementary approaches to evaluating measurement fairness (Chen, 2007; Cheung & Rensvold, 2002; Finch, 2005). DIF analysis examines whether individual items function differently across groups after controlling for the latent trait, identifying specific items that may be biased. Measurement invariance testing through multi-group CFA examines whether the overall measurement model holds across groups at three progressively restrictive levels: *configural invariance* (the same factors exist in both groups), *metric invariance* (items relate equally strongly to the factors in both groups), and *scalar invariance* (the scale origin is

identical, so mean scores can be directly compared across groups).

For ordinal items, the weighted least squares mean and variance adjusted (WLSMV) estimator—a robust estimation method designed for categorical data—is recommended for CFA (Flora & Curran, 2004). Because ordinal items have discrete response categories rather than continuous scales, threshold-based invariance testing (which models the boundaries between response categories) replaces intercept-based approaches. The conventional criteria for evaluating invariance steps use changes in fit indices rather than chi-square difference tests, which are sensitive to sample size: $\Delta CFI \leq .01$ and $\Delta RMSEA \leq .015$ indicate that the more constrained model does not fit meaningfully worse (Chen, 2007; Cheung & Rensvold, 2002).

In the context of HPT measurement, establishing scalar invariance across ideology groups would mean that the factor structure, loadings, and item thresholds are equivalent for students with different political attitudes—a necessary condition for concluding that observed score differences (or the lack thereof) reflect true construct differences rather than measurement artifacts.

2.5 The Present Study

This study addresses two interrelated measurement questions:

1. What psychometric evidence does the Czech adaptation of the Hartmann and Haselhorn HPT instrument provide, including evidence concerning a correlated three-factor representation, score reliability, and convergence with historical knowledge?
2. What evidence do DIF, measurement-invariance, and regression analyses provide

about whether scores are affected by students' political attitudes?

The study and analysis plan were preregistered. The present measurement-focused organization, the six-item contextualization composite as the primary outcome, and several analyses were adopted after registration, and not all registered analyses were implemented. Table S5 maps the registered hypotheses, omissions, and post-registration additions; findings from the latter are treated as exploratory or descriptive rather than as preregistered tests.

3. Method

3.1 Adaptation Process

The Czech HPT instrument was developed through a systematic translation and adaptation process following ITC guidelines (International Test Commission, 2017). Two bilingual Czech-English experts conducted independent forward translations from the German instrument reported in Hartmann (2008); wording was cross-checked against the published English validation article (Hartmann & Hasselhorn, 2008). An independent backward translation was produced by a third bilingual expert unfamiliar with the original. Five Czech history educators at the secondary level reviewed the adapted items for conceptual equivalence, age-appropriateness, and curricular alignment. No items required substantive modification; minor wording adjustments were made to two items for naturalness in Czech. Reviewers judged the scenario content accessible to Czech secondary students given the curriculum coverage described in Section 2.2. This was expert-review evidence, not direct evidence from student interviews.

The adaptation preserved the four-point response format (1 = *strongly disagree* to 4 = *strongly agree*), the three item categories (three items per category), and reverse-scoring of POP items from the German source. All deviations from the original were documented transparently in the OSF repository (<https://doi.org/10.17605/OSF.IO/YNG37>). The author separately cross-checked the scenario against the Czech history curriculum, but no direct student response-process study was conducted.

No cognitive pilot study (e.g., think-aloud interviews) was conducted prior to main data collection, which constitutes a limitation of the adaptation process (see Section 5.6).

3.2 Participants

The sample comprised 293 students from 20 classrooms across 10 schools in the Czech Republic, spanning lower-secondary (International Standard Classification of Education [ISCED] level 2, approximately ages 11–15; $n = 87$, 29.7%) and upper-secondary (ISCED 3, approximately ages 15–19; $n = 206$, 70.3%) levels. The inclusion criterion was completion of the curricular unit on the interwar period. Schools were drawn from five Czech regions (Praha: 42.7%; Královéhradecký: 34.8%; Zlínský: 11.3%; Jihomoravský: 8.2%; Ústecký: 3.1%) and three funding categories (public: 90.8%; private: 6.5%; church-affiliated: 2.7%). Gender composition was 192 male (65.5%), 88 female (30.0%), and 13 identifying as another gender (4.4%). Students' most recent history grade averaged 1.71 ($SD = 0.92$; Czech scale: 1 = excellent, 5 = failing).

Schools were recruited through convenience sampling; the sample over-represents upper-secondary students relative to the national age cohort composition and should

not be treated as a probability sample of Czech adolescents. Sample size was determined by an a priori power analysis specified in the preregistered protocol (OSF: <https://doi.org/10.17605/OSF.IO/YNG37>), targeting 80% power to detect standardized ideology effects of $\beta \geq .15$ in a two-level multilevel regression; the achieved $N = 285$ – 293 met that regression target. The calculation did not establish power for the post-registration DIF or MG-CFA analyses. Within each school, all participating students present on the day of administration completed the instrument battery during a regular class period (approximately 30–40 minutes). Teachers were present during administration but did not intervene in students' responses.

The sample's right-authoritarian attitude median was 2.33 on the five-point scale, and the historical-knowledge median was 3 of 6; fuller distributions appear in Section 4.4. No defensible student-, family-, or school-level socioeconomic indicator was collected. Consequently, the sample's socioeconomic composition and any associated selection bias cannot be characterized.

3.3 Instruments

3.3.1 Historical Perspective Taking (HPT) Students completed the Czech adaptation of the scenario-based HPT instrument from the German dissertation (Hartmann, 2008), with the published English account used as supporting validation evidence (Hartmann & Hasselhorn, 2008). They read a narrative in which Hannes discusses Germany's crisis and the 1930 election, then judged nine explanations of his situation, including whether he could vote for an anti-democratic party such as the NSDAP, on a 4-point Likert scale.

Three items each tapped present-oriented perspective (POP1–POP3), role of the historical agent (ROA1–ROA3), and historical contextualization (CONT1–CONT3). POP items capture present-centered judgments of the historical figure; these are reverse-scored (5 – POP, yielding a reversed range of 1–4) so that higher scores indicate less present-oriented reasoning. ROA items explain action through familiar or stereotyped social roles. CONT items require students to situate the historical figure’s deliberation within the specific political, economic, and social conditions of the Weimar Republic. The primary six-item contextualization composite was the mean of reversed present-oriented perspective and contextualization scores and therefore represents the continuum between these two response categories. The nine-item total score (adding the theoretically less certain role-of-the-agent category) served only as a secondary sensitivity outcome.

3.3.2 Right-Authoritarian Ideology (FR-LF mini) A six-item short form of the Fragebogen Rechtsextremer Einstellungen—Leipziger Form (Questionnaire on Right-Wing Extremist Attitudes—Leipzig Form; Decker, Kiess, & Brähler, 2013), comprising acceptance of right-wing dictatorship (RD; 3 items) and National Socialist sympathy/relativization (NS; 3 items) facets, rated on a 5-point scale. The NS facet is theoretically the most direct operationalization of potential content congruence with the Weimar scenario.

3.3.3 Authoritarianism (KSA-3) The nine-item Kurzskala Autoritarismus (Short Scale of Authoritarianism; Beierlein, Asbrock, Kauff, & Schmidt, 2014), measuring authoritarian aggression, submission, and conventionalism on a 5-point scale. This instrument was used for a supplementary measurement invariance check using an alternative ideology

operationalization.

3.3.4 Historical Knowledge (KN) Six multiple-choice items covering content relevant to the HPT scenario, scored dichotomously (sum score 0–6). This measure served as a convergent validity criterion, given the theoretical expectation that HPT is a knowledge-dependent competence.

3.3.5 Social Desirability (SDR-5) The five-item short form (Hays, Hayashi, & Stewart, 1989), rated on a 5-point scale with items SDR2–SDR4 reverse-coded. Included to evaluate whether HPT scores reflect impression management rather than genuine reasoning. The source studies for the FR-LF included German respondents aged 14 years and older, whereas KSA-3 was developed for German-speaking adults aged 18 years and older and SDR-5 with adult medical outpatients and older adults. None therefore constitutes direct Czech adolescent validation; suitability rests on expert review and the sample-specific evidence reported here and in Table S4.

3.4 Analytic Approach

All analyses were conducted in R (version 4.4.2) using lavaan for CFA, mirt for IRT-based DIF analysis, psych for reliability estimation, and lme4/performance for intraclass correlations.

Factor structure. CFA compared one-factor (general HPT), two-factor (POP+CONT vs. ROA), and three-factor (POP, ROA, CONT) models using the WLSMV estimator, appropriate for ordinal item responses (Flora & Curran, 2004). CFA fit indices summarize

how well a hypothesized factor structure reproduces the observed correlations among items; multiple indices are reported because each captures a different aspect of misfit. Model evaluation used CFI ($\geq .95$ acceptable, $\geq .97$ good), the Tucker–Lewis Index (TLI; $\geq .95$), the Root Mean Square Error of Approximation (RMSEA; $\leq .08$ acceptable, $\leq .05$ good), and the Standardized Root Mean Square Residual (SRMR; $\leq .08$).

Reliability. Internal consistency was assessed using raw and polychoric Cronbach’s α , McDonald’s ω , and KR-20 for the dichotomous knowledge items. Reliability of the combined ideology score was estimated with the Mosier formula. Full methods and estimates are reported in Table S3.

Intraclass correlations. We computed intraclass correlation coefficients (ICCs) at the school and classroom levels to characterize the multilevel structure of the data and to evaluate whether clustering warranted multilevel approaches.

Clustered data handling. The substantive regressions used random intercepts for the nested data. The DIF, MG-CFA, and zero-order correlation analyses treated observations as independent. Composite score ICCs do not establish that item thresholds, loadings, or their standard errors are unaffected by clustering; therefore, uncertainty for these analyses may be understated. The zero-order correlation intervals are reported as descriptive, unadjusted intervals rather than cluster-robust inference.

Missing data and score construction. Composite scores required at least two answered items per three-item HPT subscale, four of six FR-LF items, seven of nine KSA-3 items, and four of five SDR-5 items; available responses were averaged. Missing knowledge responses were scored as incorrect, following the original analysis scripts. Reliability estimates used

listwise-complete item sets, while correlations used pairwise-complete composite scores. These rules explain the analysis-specific sample sizes reported in the tables and supplement.

Differential item functioning. Low and High ideology groups were formed post-registration using tertile splits on a composite ideology score (mean of z-scored FR-LF and KSA-3), with the middle tertile excluded (Low $n = 96$; High $n = 95$). A constrained unidimensional multi-group graded response model (GRM item discrimination and category-intercept parameters for each item by group are reported in Table S1 in the OSF supplementary materials) using a sequential item-release design tested each item for omnibus DIF by jointly freeing its discrimination and category intercepts, with Bonferroni correction ($\alpha = .01$). The baseline model constrains all nine items to equality across groups; each test then frees the discrimination and category intercepts for the focal item, yielding a likelihood-ratio comparison against the fully constrained baseline (an all-others-as-anchor strategy). This approach assumes that the remaining eight items are DIF-free when testing each focal item; iterative purification was not applied, which means that if multiple anchor items exhibited small DIF, focal-item detection could be affected. Because the CFA favoured correlated dimensions, the unidimensional GRM is a pragmatic sensitivity model rather than a fully aligned measurement model; multidimensionality or local dependence may affect the item tests.

Sensitivity of DIF detection. With approximately 96 respondents per ideology group and nine Bonferroni-adjusted tests, statistical power was limited. No design-specific simulation was conducted, so the minimum detectable DIF magnitude is unknown. The extreme-

group design increases ideological contrast at the cost of excluding the middle tertile and reducing group size.

Multi-group CFA. Stepwise MG-CFA tested configural, metric, and scalar invariance across ideology groups using the three-factor model with WLSMV estimation. Invariance was evaluated using $\Delta CFI \leq .01$ and $\Delta RMSEA \leq .015$ criteria (Chen, 2007; Cheung & Rensvold, 2002).

Substantive models. Random-intercept linear models predicted each standardized HPT outcome from standardized FR-LF, KSA-3, historical-knowledge, and SDR-5 scores entered together, with intercepts for school and classroom. Thus, each reported ideology coefficient is mutually adjusted for the other ideology measure, knowledge, social desirability, and the nested grouping structure.

Convergent validity. Descriptive Pearson correlations between HPT composites and historical knowledge provided convergent validity evidence; Fisher-transformed intervals did not adjust for clustering.

Supplementary invariance check. To verify that invariance findings were not an artifact of the composite ideology definition, MG-CFA was also conducted using NS-only grouping (the facet most directly content-congruent with the Weimar scenario).

4. Results

The Results follow the two measurement questions in sequence. Sections 4.1–4.5 assess factor structure, score precision, distributions, and clustering; Sections 4.6–4.8 examine item

and model-level fairness; Sections 4.9–4.10 then report the focal knowledge and ideology relationships.

4.1 Factor Structure

CFA supported the three-factor model (POP, ROA, CONT) as best-fitting, outperforming the two-factor and one-factor alternatives (Table 1). The three-factor model showed excellent global fit: CFI = .999, TLI = .998, RMSEA = .011 (90% CI [.000, .051]), SRMR = .048. The two-factor model combining POP and CONT items on a single factor showed acceptable but inferior fit (CFI = .956, RMSEA = .057), while the one-factor model fit poorly (CFI = .926, RMSEA = .073).

Table 1. CFA Fit Indices for HPT Factor Models (WLSMV Estimator)

Model	χ^2	df	CFI	TLI	RMSEA	90% CI	SRMR
1-Factor	66.68	27	.926	.902	.073	[.051, .095]	.075
2-Factor (POP+CONT, ROA)	49.48	26	.956	.940	.057	[.032, .081]	.066
3-Factor (POP, ROA, CONT)	24.78	24	.999	.998	.011	[.000, .051]	.048

Note. WLSMV = weighted least squares mean and variance adjusted. All items treated as ordered categorical. The 2-factor model groups POP and CONT items on a single factor with ROA on a separate factor. Chi-square values are mean-and-variance adjusted (WLSMV). Nested model comparisons require the DIFFTEST procedure rather than standard chi-square difference tests. All $p < .001$ except the three-factor model ($p = .418$).

The near-perfect global fit of the three-factor model reflects the small item set (nine items

in three just-identified three-indicator factors—each subscale has exactly as many free parameters as observed statistics, leaving no room for misfit within subscales) and should be interpreted alongside local fit diagnostics: the largest modification index was 7.35 (POP1–ROA3 residual covariance; below the threshold of 10), and standardized residual correlations were small ($|r| \leq .13$). With only three indicators per factor, there is limited opportunity to reveal within-factor misfit; the near-perfect CFI is therefore a structural consequence of the low- df specification rather than evidence of an unusually well-fitting model. The Czech data are compatible with the correlated three-factor specification, but this is not a test of cross-national equivalence.

Inter-factor correlations from the three-factor CFA were: POP–ROA $\Phi = .377$, POP–CONT $\Phi = .509$, ROA–CONT $\Phi = .631$. These moderate-to-strong correlations and the better fit of the three-factor model provide internal-structure evidence that the item sets are distinguishable in this sample. They do not by themselves establish discriminant validity. Stronger evidence would require showing that the subscales relate differentially to external criteria in theoretically expected ways.

A supplementary bifactor model (one general factor plus three specific factors, in which each item loads on both the general factor and its subscale-specific factor) fit well ($\chi^2 = 14.70$, $df = 18$, $p = .682$) but did not meaningfully improve over the correlated three-factor model ($\Delta CFI = .001$). The low df (18) results from the additional cross-loadings consuming degrees of freedom, and the comparison with the correlated three-factor model ($df = 24$) should be treated cautiously given the different parameterisations. CONT items loaded primarily on the general factor (.47–.63), while POP and ROA retained meaningful

specific factor variance, supporting subscale-level interpretation.

4.2 Standardized Factor Loadings

Table 2 presents the standardized loadings from the three-factor CFA. CONT items loaded most strongly (.61–.72), followed by POP items (.30–.74) and ROA items (.30–.67). POP2 showed the weakest loading (.30), at the conventional minimum threshold for item retention; it was retained to preserve fidelity to the original instrument structure.

Table 2. *Summary of Standardized Factor Loadings*

Subscale	Loading range	Weakest item
Present-oriented perspective	.30–.74	POP2 (.30)
Role of historical agent	.30–.67	ROA2 (.30)
Historical contextualization	.61–.72	CONT2 (.61)

Note. POP items are reverse-scored (higher = more contextualized reasoning). All loadings were significant at $p < .001$. Full item estimates, standard errors, and confidence intervals are reported in Table S2.

4.3 Reliability and Internal Consistency

Table 3 summarizes reliability for the primary study scores. Across HPT subscales, raw Cronbach's α ranged from .46 to .64 and McDonald's ω from .54 to .70. Full estimates for all HPT and predictor scores are in Table S3.

Table 3. *Reliability Summary for Primary Study Scores*

Score	Items/components	Reliability	Method
HPT composite	6	.66	ω total
HPT total	9	.70	ω total
Combined ideology	2 scales	.80	Mosier

Note. The Mosier estimate has a 95% bootstrap CI [.74, .84]. Full subscale and predictor alpha, polychoric-alpha, omega, and interval estimates are reported in Table S3.

Reliability was modest and constrains individual interpretation. FR-LF had $\alpha = .67$, KSA-3 had $\alpha = .72$, and the combined ideology score had estimated reliability .80, 95% CI [.74, .84]. Knowledge had KR-20 = .55, and SDR-5 was weak ($\alpha = .30$).

4.4 Descriptive Statistics

Table 4 presents descriptive statistics. HPT scores followed the expected mean-score ordering: reversed present-oriented perspective scores were highest, followed by role-of-the-agent and contextualization scores. Contextualization produced the lowest scores ($M = 2.71$); this ordering may reflect item endorsement or difficulty and is not developmental evidence. Right-authoritarian attitude scores (FR-LF) and authoritarianism scores (KSA-3) were below their scale midpoints ($M = 2.48$ and 2.86 , respectively). The right-authoritarian attitude median was 2.33 (IQR [2.00, 3.00]) and 51 of 284 students (18.0%) scored above its midpoint. The authoritarianism median was 2.89 (IQR [2.53, 3.22]) and 106 of 283 students (37.5%) scored above its midpoint. On the mean of the two raw scales, 71 of 283 students (25.1%) scored above 3. Historical knowledge had a median of 3 (IQR

[2, 4]), with 4.1% at the floor and 8.9% at the ceiling. No defensible student- or school-level socioeconomic measure was available.

Table 4. *Descriptive Statistics for Study Variables*

Variable	<i>n</i>	<i>M</i>	<i>SD</i>	Min	Max
Present-oriented perspective (reversed)	287	2.97	0.64	1.33	4.00
Role of the historical agent	287	2.80	0.68	1.00	4.00
Historical contextualization	287	2.71	0.74	1.00	4.00
Six-item contextualization composite	287	2.84	0.55	1.33	4.00
Nine-item HPT total score	287	2.83	0.49	1.67	3.89
Historical knowledge (0–6)	293	3.04	1.62	0.00	6.00
Dictatorship acceptance	285	2.54	0.88	1.00	5.00
Nazi-crime relativization	286	2.43	0.89	1.00	5.00
Right-authoritarian attitudes	284	2.48	0.75	1.00	5.00
Authoritarianism	283	2.86	0.62	1.00	4.60
Social desirability	283	3.02	0.63	1.00	4.60

Note. HPT items scored on a 1–4 scale; POP items reverse-coded. FR-LF and KSA-3 scored on a 1–5 scale. KN scored as sum of correct responses (0–6).

4.5 Intraclass Correlations

Intraclass correlations indicated meaningful school-level clustering for most HPT outcomes (six-item contextualization composite: ICC_school = .041; nine-item total

score: ICC_school = .085; role of the historical agent: ICC_school = .102), consistent with between-school differences in instructional emphasis and student composition. Classroom-level variance was near zero for the primary composite but non-negligible for contextualization (ICC_class = .033) and role of the historical agent (ICC_class = .104). These ICCs justify multilevel modelling for substantive analyses. The school-level variance is consistent with between-school differences in history instruction, curricular emphasis, and student composition, although the present design cannot identify which of these mechanisms produced the variation.

4.6 DIF Analysis

Table 5 presents omnibus DIF results for all nine HPT items. Using a constrained multi-group graded response model with likelihood-ratio tests and Bonferroni-adjusted significance ($\alpha = .01$), no items were flagged. All adjusted p -values exceeded .01. No DIF was detected between the low- and high-ideology groups with this sample and procedure; the magnitude that the design could reliably detect is unknown.

Table 5. *DIF Results per HPT Item (Likelihood-Ratio Tests from Multi-Group Graded Response Model)*

Item	χ^2	df	p (raw)	p (Bonferroni)	Flagged
POP1	10.46	4	.033	.300	No
POP2	9.01	4	.061	.547	No
POP3	9.72	4	.045	.408	No
ROA1	9.59	4	.048	.432	No

Item	χ^2	df	p (raw)	p (Bonferroni)	Flagged
ROA2	3.13	4	.536	1.000	No
ROA3	8.25	4	.083	.744	No
CONT1	1.51	4	.825	1.000	No
CONT2	3.60	4	.462	1.000	No
CONT3	9.63	4	.047	.424	No

Note. Likelihood-ratio chi-square statistics from constrained multi-group graded response models. Each test compares a fully constrained baseline (all items equal across groups) to a model freeing discrimination and category-intercept parameters for the tested item. Low ($n = 96$) and High ($n = 95$) ideology groups formed by tertile split on composite ideology score (middle tertile excluded). Bonferroni-adjusted $\alpha = .01$ (9 tests). 0 of 9 items flagged. POP1 showed the largest DIF statistic ($\chi^2 = 10.46, p_{\text{raw}} = .033$), well above the Bonferroni threshold after correction ($p_{\text{adj}} = .300$). GRM item discrimination and category-intercept parameters are reported in Table S1 in the OSF supplementary materials.

Because every other item served as an anchor, undetected DIF among those anchors could affect each test. The result should therefore be interpreted as “no DIF detected with this sample and procedure,” not “no DIF present.”

4.7 Measurement Invariance

Table 6 presents the stepwise MG-CFA results. The configural model produced CFI = .977, RMSEA = .044, and SRMR = .074. Adding equality constraints did not worsen global

fit: metric $\Delta\text{CFI} = -.001$ and $\Delta\text{RMSEA} = -.001$; scalar $\Delta\text{CFI} = +.005$ and $\Delta\text{RMSEA} = -.008$. These changes fall within common fit-index criteria (Chen, 2007; Cheung & Rensvold, 2002). All three models converged and passed lavaan's post-estimation admissibility check; the diagonals of their model-implied residual-variance matrices were positive.

Table 6. *Multi-Group CFA Fit Indices Across Invariance Levels (WLSMV)*

Model	CFI	RMSEA	SRMR	ΔCFI	ΔRMSEA
Configural	.977	.044	.074	—	—
Metric	.976	.043	.081	-.001	-.001
Scalar	.981	.035	.076	+.005	-.008

Note. ΔCFI and ΔRMSEA computed relative to the preceding model. Invariance criteria: $|\Delta\text{CFI}| \leq .01$, $|\Delta\text{RMSEA}| \leq .015$ (Chen, 2007). Low and High ideology groups formed by tertile split on composite ideology; complete item-response data were available for 92 Low and 90 High participants. Items treated as ordered categorical.

The SRMR increased slightly from configural (.074) to metric (.081), marginally exceeding the conventional $\leq .08$ threshold. This threshold was developed for maximum-likelihood estimation with continuous indicators and may not apply directly to WLSMV-estimated models with polychoric residuals; the marginal exceedance should therefore be interpreted cautiously. The SRMR returned to .076 at the scalar step. The largest ordinary modification index at the metric step was 11.22 and suggested a POP2 cross-loading on the ROA factor in the Low group. Because ordinary modification indices ignore equality

constraints, this is a local cross-loading diagnostic, not evidence of a between-group loading difference.

The admissible solutions and changes in CFI and RMSEA are compatible with scalar invariance under the fitted model. This remains qualified evidence rather than a firm equivalence conclusion: the analysis was added after registration, used only 90–92 complete cases per extreme group, estimated three-indicator factors, and did not model school or classroom clustering.

4.8 Supplementary Invariance: NS-Only Grouping

To verify that invariance findings were not an artefact of the composite ideology grouping variable, we repeated the MG-CFA using groups defined by the NS facet alone (National Socialist sympathy/relativization), which represents the most direct theoretical operationalization of content congruence with the Weimar scenario. With the NS tertile split, group sizes were $n = 126$ (Low) and $n = 123$ (High), with 37 middle-tertile cases and 7 missing NS scores excluded. Fit did not deteriorate when equality constraints were added (configural CFI = .959, RMSEA = .051, SRMR = .071; metric Δ CFI = +.002, Δ SRMR = +.006; scalar Δ CFI = +.014, Δ SRMR = −.003). Because CFI increased and RMSEA and SRMR decreased at the scalar step, the positive Δ CFI does not indicate worse fit and should not be compared with a deterioration threshold by absolute magnitude. This post-registration analysis provides descriptive robustness evidence, not a second confirmatory test. Full fit statistics for this supplementary analysis are available in the OSF repository.

4.9 Convergent Validity

Scenario-relevant historical knowledge correlated positively with all HPT outcomes: $r = .34$ for the six-item contextualization composite, $r = .22$ for contextualization, and $r = .32$ for reversed present-oriented perspective. These moderate correlations indicate that students with stronger knowledge of the relevant historical period scored higher on HPT. The scores were not empirically interchangeable, but their unshared variance cannot be attributed specifically to reasoning because it also includes measurement error and other unmeasured influences. A limitation of this evidence is that the KN items were written to cover content directly relevant to the HPT scenario, so the correlation may partly reflect shared specific-content activation rather than the broader “knowledge-dependent competence” relationship posited theoretically. A general historical knowledge measure would provide a stronger convergent validity test.

History grade also correlated with the six-item contextualization composite ($r = -.153$, $p = .010$; negative sign reflects the Czech scale where 1 = excellent). By contrast, right-authoritarian attitudes showed a negligible correlation with the composite ($r = -.05$), and social desirability was unrelated to HPT outcomes ($r = -.02$ to $.01$). One exploratory exception was a negative association between authoritarianism and reversed present-oriented perspective ($r = -.13$, 95% CI $[-.25, -.02]$). The corresponding mutually adjusted standardized KSA-3 coefficient was $\beta = -.166$, $SE = .066$, unadjusted $p = .013$. This association was not preregistered or subjected to the preregistered multiplicity procedure and should be treated as a hypothesis-generating pattern consistent with the reduced-integrative-complexity pathway rather than a confirmed effect. Overall, the

positive knowledge associations and absence of detected associations for the primary ideology–HPT relationship are consistent with, but do not establish, the intended score interpretation.

Table 7. *Zero-Order Pearson Correlations Among Key Variables*

	HPT	Context	Presentism (reversed)	Knowledge	Right-authoritarian attitudes	Authoritarianism	Social desirability
HPT composite	—	[.78, .86]	[.71, .81]	[.23, .43]	[−.16, .07]	[−.15, .09]	[−.14, .10]
Contextualization	.82***	—	[.14, .36]	[.11, .33]	[−.10, .13]	[−.05, .19]	[−.11, .13]
Present-oriented perspective (rev.)	.76***	.26***	—	[.20, .41]	[−.21, .02]	[−.25, −.02]	[−.16, .07]
Knowledge	.34***	.23***	.31***	—	[−.22, .01]	[−.07, .16]	[−.09, .15]
Right-authoritarian attitudes	−.05	.02	−.10	−.10	—	[.43, .60]	[−.30, −.08]
Authoritarianism	−.03	.07	−.13*	.05	.52***	—	[−.26, −.03]
Social desirability	−.02	.01	−.05	.03	−.19**	−.15*	—

Note. Correlations are below the diagonal and unadjusted descriptive 95% confidence intervals are above it. Pairwise complete observations ($n = 282$ – 287 ; exact values in Table S3b). Present-oriented perspective is reverse-scored. Knowledge = historical knowledge (0–6 sum); FR-LF = right-authoritarian ideology (1–5); KSA-3 = authoritarianism (1–5); SDR-5 = social desirability (1–5). Intervals and p -values do not adjust for school or classroom clustering. *** $p < .001$. ** $p < .01$. * $p < .05$.

Figure 1 visualizes the near-zero ideology association and positive knowledge association with the six-item contextualization composite.

Figure 1: Observed relationships of the six-item contextualization composite with the combined ideology score—the mean of standardized right-authoritarian attitude and authoritarianism scores—(Panel A) and historical knowledge (Panel B). Points are jittered to display overlap; lines and shaded regions show unadjusted linear fits and 95% confidence intervals.

4.10 Substantive Context: Ideology-HPT Relationships

The mutually adjusted standardized right-authoritarian attitude coefficient was near zero for the primary six-item contextualization composite: $\beta = .016$, $SE = .068$, 95% CI $[-.117, .149]$, $p = .817$ (analysis $n = 282$). The fitted model issued a singularity warning because the classroom random-intercept variance was estimated as zero; the school intercept and fixed effects remained estimable, and school fixed-effects sensitivity models gave the same substantive conclusion. Historical knowledge was the only consistent predictor ($\beta = 0.21$ – 0.34 , $p < .001$). As an exploratory sensitivity analysis, equivalence tests used the Two One-Sided Tests (TOST) procedure, which reverses the logic of null-hypothesis testing by asking whether an effect is small enough to be declared practically negligible. The Smallest Effect Size Of Interest (SESOI) was set post hoc at ± 0.20 standardized units, cor-

responding to Cohen’s (1988) threshold for a “small” effect. This SESOI is wider than the preregistered power target of $\beta \geq .15$, meaning that effects between .15 and .20 cannot be confidently excluded; the TOST results should therefore be treated as exploratory rather than confirmatory. With the ± 0.20 boundary, the TOST results indicated that right-authoritarian attitude effects at or above $\beta = .20$ are statistically ruled out for the primary relationship (TOST $p = .0034$; 90% CI $[-.096, .127]$, entirely within the ± 0.20 SESOI). The right-authoritarian attitude coefficient for the primary composite remained non-significant across all sensitivity checks, including alternative HPT scoring composites, different ideology operationalizations, exclusion of high social desirability responders, random-slope models, and school fixed-effects specifications. These substantive findings complement the measurement evidence: no DIF or composite-level ideology association was detected within the observed ideological range.

5. Discussion

5.1 Summary of Findings

The results provide qualified fairness evidence. The expected factor structure was supported, no DIF was detected with this procedure, and right-authoritarian attitudes did not predict the primary HPT composite; fit-index changes were compatible with scalar invariance, subject to small extreme groups and unmodelled clustering. The Czech adaptation showed modest subscale reliability, a positive relationship with scenario-relevant historical knowledge, and sensitivity to school-level variation. An unadjusted exploratory authoritarianism–reversed-presentism association was not subjected to the preregistered

multiplicity procedure; other ideology and social-desirability associations were not detected, although weak reliability constrains the latter null associations.

5.2 Factor-Structure Evidence

The correlated three-factor model (POP, ROA, CONT) fit the Czech data better than the tested alternatives. This does not demonstrate cross-cultural equivalence, and the specification differs from the two-dimensional PCA pattern in the original German study. It shows only that the Czech data are compatible with separating the three item sets, under a near-saturated model with limited opportunity to reveal misfit. CONT items loaded most consistently (.61–.72), while POP2 and ROA2 showed weaker loadings (.30); these were retained for comparability but are candidates for revision in future adaptations.

5.3 Addressing Modest Reliability

The subscale reliabilities ($\alpha = .46-.64$; $\omega = .53-.70$) fall below conventional benchmarks and limit individual-level interpretation. Three-item scales make high coefficients difficult to attain, but brevity does not make the observed precision adequate. Loevinger (1957) cautioned that highly homogeneous item sets can reduce a construct to repeated versions of a narrow question and argued for broad content representation; that principle supports balancing coverage and homogeneity, not treating low reliability as harmless. The six- and nine-item HPT scores were more precise ($\omega = .66$ and $.70$), so we recommend composite scores rather than individual subscales for group-level research. Associations involving the least reliable measures, especially SDR-5, should be read cautiously because attenuation may obscure weak relationships.

5.4 Measurement Fairness Evidence

Fit-index changes were compatible with scalar invariance for both ideology groupings, and the composite-group models were admissible in the current reproducible analysis. The small extreme groups, unmodelled clustering, and post-registration status nevertheless prevent a firm equivalence conclusion. The DIF analysis adds item-level evidence, but no design-specific power analysis was conducted and the unidimensional GRM does not match the CFA structure. Together, these results provide qualified rather than definitive fairness evidence.

The correlation pattern—positive scenario-relevant knowledge–HPT associations (Chapman, 2021; Hartmann & Hasselhorn, 2008; Wineburg, 2001), a near-zero primary ideology correlation, and null social desirability correlations—is consistent with the intended score interpretation (American Educational Research Association et al., 2014; Messick, 1995). However, the convergent evidence is bounded by the scenario-proximal nature of the knowledge measure (see Section 4.9), which limits the strength of the knowledge-dependent competence claim.

The near-zero ideology–HPT correlation ($r = -.05$) should not be interpreted as conclusive evidence that ideology plays no role in HPT performance. As discussed in Section 2.3, two opposing pathways are theoretically plausible: a congruence pathway (whereby attitudinal alignment inflates scores) and a reduced integrative complexity pathway (whereby authoritarian cognition depresses contextualization). If both pathways operate simultaneously, their effects could cancel, producing a near-zero net correlation that masks two moderate-sized opposing effects. The present data cannot distinguish a

genuine null from cancelling pathways.

The present fairness evidence applies to mainstream Czech adolescent samples with restricted ideological range. Users in contexts with greater political polarization should conduct their own DIF and invariance analyses before assuming equivalent measurement.

5.5 Implications for Assessment Practice

The core practical message is that politically charged assessment content need not produce detectable construct-irrelevant variance in every application. In this study, no primary composite association or DIF flag was detected at the available sensitivity. This pattern is bounded by the restricted ideological range and should not be generalized beyond the single structured, closed-ended scenario without further evidence.

The evaluation protocol used here illustrates a possible workflow for evaluating fairness when assessment content intersects with respondents' attitudes. Although developed for HPT, the workflow may inform studies of other scenario-based assessments where content carries attitudinal valence. The general approach involves five steps:

1. Identify the attitudinal dimension theoretically most likely to produce CIV.
2. Form extreme groups on that dimension.
3. Test DIF at the item level.
4. Test measurement invariance at the model level.
5. Examine a prespecified set of expected relationships, including whether HPT dimensions relate differentially to external outcomes as theory predicts.

The format itself may be a fairness mechanism. If scenario-based formats channel delibera-

tive processing and override automatic attitude-retrieval (Evans & Stanovich, 2013), then the instrument format—not just the construct—buffers against motivated reasoning. However, this hypothesis has an important implication: if the format itself suppresses attitudinal responding, then the present fairness conclusion is conditional on the closed-ended Likert format and cannot be extended to open-ended HPT assessments where ideology could operate through different cognitive pathways.

Several design features may explain the instrument’s resistance to attitudinal contamination: the scenario provides contextual information that channels deliberative processing, the Likert items require evaluating propositions about a historical figure rather than expressing personal attitudes, and the school assessment context may activate an academic frame. These are hypotheses, not conclusions—the present study was not designed to test them experimentally, and doing so would require comparing structured and open-ended formats using the same content.

An alternative explanation for the compatible invariance fit pattern deserves consideration. In a school context where the scenario involves a Nazi-adjacent historical figure, students may uniformly avoid endorsing presentist responses—not because they are engaging in genuine historical reasoning, but because contextualization is the socially safe response regardless of one’s actual political attitudes. If task-demand compliance produces equivalent response patterns across ideology groups, the resulting apparent invariance would reflect shared social desirability pressure rather than genuine absence of ideological influence on reasoning. The null SDR-5 correlations provide partial evidence against this interpretation, but a brief self-report measure of social desirability may not capture the

specific task demands operating in a classroom assessment of politically sensitive historical content.

5.6 Limitations

Several limitations qualify these findings.

1. *Single country and scenario.* Nine ratings of one Weimar scenario do not provide nine independent samples of the HPT content domain, so scenario-specific wording, knowledge, or moral salience cannot be separated from HPT. Future studies should use multiple scenarios spanning different periods, places, and political contexts.
2. *Restricted ideological range.* Depending on the measure, 18.0% (FR-LF), 37.5% (KSA-3), or 25.1% (their raw-score mean) of respondents scored above the scale midpoint, so the DIF and invariance analyses compare moderately elevated to low ideology, not genuine political extremism. The null ideology finding should be interpreted as “no evidence of CIV in this range-restricted sample” rather than as a general demonstration that politically charged content is fair.
3. *Limited DIF power.* With $n \approx 96$ per group, DIF power was limited. A formal power simulation for the GRM likelihood-ratio test at Bonferroni-corrected α was not conducted, so the minimum detectable DIF magnitude is unknown.
4. *Gender imbalance.* The sample was 65.5% male, and no DIF or sensitivity analysis by gender was conducted. The fairness conclusion should therefore be replicated in a more gender-balanced sample.

- 740 5. *Convenience sampling and unavailable socioeconomic data.* The sample over-represented
741 upper-secondary students and was not probabilistic. Because no defensible socioe-
742 conomic indicator was collected, neither socioeconomic coverage nor selection along
743 that dimension can be assessed.
- 744 6. *Modest reliability.* Subscale reliabilities ($\alpha = .47-.64$) constrain individual-level score
745 interpretations; future adaptations should consider expanding subscale length.
746 Omega hierarchical (ω_h) from the bifactor model was not computed; this index
747 would clarify what proportion of subscale variance is attributable to the general
748 HPT factor versus specific subscale factors.
- 749 7. *Method and format constraints.* All measures were self-report instruments adminis-
750 tered in a single session. The closed-ended Likert format may not generalise to open-
751 ended HPT assessments where ideology could operate through different cognitive
752 mechanisms (Smith, 2017; Smith, Breakstone, & Wineburg, 2018).
- 753 8. *No response process evidence.* Think-aloud or cognitive- interview studies, extending
754 Huijgen et al. (2017), could compare the same content in rating and open-response
755 formats. Evidence use and integration of conflicting historical considerations would
756 support contextual reconstruction; explicit moral evaluation or affective engagement
757 would identify processes outside this instrument's narrow cognitive scoring target;
758 paraphrase and option- matching comments would indicate format-driven respond-
759 ing; and endorsement tied to one's present political position would indicate atti-
760 tude congruence. These observable indicators could distinguish pathways that the
761 present ratings cannot separate.

5.7 Recommendations

For researchers developing or adapting HPT instruments: (a) report ω alongside α for short subscales, with Spearman-Brown projections for context; (b) evaluate fairness through DIF and measurement invariance for theoretically relevant grouping variables; (c) consider revising weak-loading items (POP2, ROA2) while preserving the theoretical structure; (d) expand subscale length to improve reliability; and (e) replicate fairness evaluations across diverse samples, scenarios, and cultural contexts.

5.8 Conclusion

The Czech data were compatible with a correlated three-factor representation of the Hartmann and Hasselhorn HPT item sets and produced scores that relate to scenario-relevant historical knowledge in theoretically expected ways. Fit-index patterns were compatible with measurement invariance across ideology groups, but small extreme groups, unmodelled clustering, and post-registration analysis prevent a firm equivalence conclusion. At the sensitivity levels afforded by the present sample and in the observed ideological range, right-authoritarian attitudes were unrelated to the primary HPT composite. An unjustified exploratory authoritarianism association with one subscale was not subjected to the preregistered multiplicity procedure.

For researchers and assessment developers, the practical implication is that structured scenario-based assessments can be evaluated for attitude-related measurement differences using complementary item-, model-, and relationship-level checks. In this sample, those checks detected no bias in the primary composite at the available sensitivity. Whether this

pattern extends to more polarized populations, open-ended assessment formats, or different historical scenarios remains an open empirical question. The evaluation protocol illustrated here—CFA, DIF, MG-CFA, and a prespecified network of external relationships—provides a possible template for answering that question wherever attitudinally charged content meets competence assessment.

Data Availability Statement

De-identified data, annotated analysis scripts, the complete instrument battery (in Czech), supplementary materials, and all deviations from the original instrument are available on the Open Science Framework (<https://doi.org/10.17605/OSF.IO/YNG37>). Data are provided in machine-readable formats (RDS and xlsx) accompanied by a full variable codebook (PDF). The analysis pipeline consists of seven numbered R Markdown scripts that reproduce all reported results; a README file documents the directory structure, execution order, software requirements, and mapping of scripts to manuscript tables and figures. Supplementary materials (Tables S1–S5) are included in the OSF repository. The study design, hypotheses, and analysis plan were preregistered on OSF prior to data collection; deviations and omissions are disclosed in Table S5.

Conflict of Interest Disclosure

The author declares that he complies with the PCI rule of having no financial conflicts of interest in relation to the content of the article, and has no non-financial conflicts of interest.

Ethics Statement

This study involved secondary school students completing questionnaires during regular class periods. Under Czech law (Act No. 110/2019 Sb., on the processing of personal data), ethics committee approval is not required for non-interventional educational research involving anonymous questionnaires where no personal data are collected. Participation was voluntary; students were informed about the study's purpose and their right to decline participation without consequences. All responses were de-identified at the point of data entry. No personally identifiable information was collected or stored. The study followed the principles of the Declaration of Helsinki for research involving human participants.

Funding

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

TOP Checklist and Disclosures Form

This checklist must be completed and included as an appendix at the end of your preprint prior to submission to PCI Psychology. Manuscripts without this document included as an appendix will be returned to authors without review.

The policy of PCI Psychology is to recommend papers only if the data, methods used in the analysis, and any digital materials used to conduct the research are clearly and precisely documented and are maximally available to any researcher for purposes of reproducing the results or replicating the procedure. PCI Psych follows the principle of “as open as possible, as closed as necessary.”

First author name (last/family, first/given): Kaleta, Juda

Preprint DOI or URL: <https://doi.org/10.17605/OSF.IO/YNG37>

Section 1: Data

Does your manuscript contain reports of any data?

☒ **Yes** (continue with next question)

☐ **No** (skip to Section 2)

Are appropriately anonymized raw data available within a trusted digital repository?

☒ **Yes, available at this link:** <https://doi.org/10.17605/OSF.IO/YNG37>

☐ **No, justification:**

998 **Are third-party data cited in the manuscript, with a DOI?** (e.g., for preexisting data, data
999 deposited in a repository)

1000 ☐ Yes, the DOI is as follows:

1001 **[X] No, justification:** The data were collected specifically for this study; no third-party
1002 datasets were used.

1003 **Is there a data dictionary and/or readme file included with the data to make it inter-**
1004 **pretable?**

1005 **[X] Yes, available at this link:** <https://doi.org/10.17605/OSF.IO/YNG37> (full variable
1006 codebook in PDF and README file)

1007 ☐ No, justification:

1008 **Do you indicate in the manuscript how the sample size was determined?**

1009 **[X] Yes.** (Section 3.4: a priori power analysis targeting 80% power to detect $\beta \geq .15$)

1010 ☐ No, justification:

1011 **Do you report all data exclusions (e.g., outliers, careless responders)?**

1012 **[X] Yes.** (Section 3.4 and Table S5: the middle ideology tertile was excluded for post-
1013 registration DIF and MG-CFA analyses; this analysis-specific exclusion is reported.)

1014 ☐ No, justification:

1015 **Do you report all inclusion/exclusion criteria and when they were established?**

1016 **[X] Yes.** (Participant eligibility is described in Section 3.2 and was preregistered; post-
1017 registration analysis-specific exclusions are described in Section 3.4 and Table S5.)

1018 ☐ No, justification:

1019 **Are all measures, questions, and/or conditions used in the study described in the**
1020 **manuscript or available in the supplemental material?**

1021 **[X] Yes.** (All instruments described in Sections 3.1–3.3; full Czech-language instrument
1022 battery available on OSF: <https://doi.org/10.17605/OSF.IO/YNG37>)

1023 ☐ No, justification:

1024 **Section 2: Analysis Scripts/Code/Codebooks**

1025 **Does your manuscript contain any analysis of quantitative or qualitative data?**

1026 **[X] Yes** (continue with next question)

1027 ☐ No (skip to Section 3)

1028 **Are third-party analysis scripts/code (e.g., R, Stata), codebooks, or other relevant doc-**
1029 **umentation available within a trusted digital repository?**

1030 **[X] Yes, available at this link:** <https://doi.org/10.17605/OSF.IO/YNG37> (7 R Mark-
1031 down pipeline scripts, 4 figure scripts, 2 supplementary analysis scripts, and a Makefile)

1032 ☐ No, justification:

1033 **Are the analysis scripts/code (e.g., R, Stata), codebooks, or other relevant documenta-**
1034 **tion cited in the manuscript, with a DOI?**

1035 **[X] Yes, the DOI is as follows:** <https://doi.org/10.17605/OSF.IO/YNG37>

1036 ☐ No, justification:

1037 **Section 3: Study Materials**

1038 **Does your manuscript contain any research materials (e.g., stimuli, programming code,**
1039 **questionnaires, interview protocols)?**

1040 **[X] Yes** (continue with next question)

1041 ☐ No (skip to Section 4)

1042 **Are all study materials and descriptions of study procedures available within a trusted**
1043 **digital repository?**

1044 **[X] Yes, available at this link:** <https://doi.org/10.17605/OSF.IO/YNG37> (Czech-
1045 language versions of all questionnaires: HPT, FR-LF, KSA-3, SDR-5, and historical
1046 knowledge test)

1047 ☐ No, justification:

1048 **Are all third-party study materials, descriptions of study procedures, or other relevant**
1049 **documents cited in the manuscript, with a DOI?**

1050 ☐ Yes, the DOI is as follows:

1051 **[X] No, justification:** Third-party instruments are cited via standard bibliography refer-
1052 ences (Hartmann & Hasselhorn, 2008; Decker et al., 2013; Beierlein et al., 2014; Hays et al.,
1053 1989); DOIs are included where available. The adapted Czech versions are deposited on
1054 OSF (<https://doi.org/10.17605/OSF.IO/YNG37>).

1055 **Section 4: Preregistration**

1056 **Were any aspects of your manuscript preregistered?**

1057 **[X] Yes** (continue with next question)

1058 ☐ No (do not complete the rest of the form)

1059 **Does the manuscript contain an accessible link to the preregistration?**

1060 **[X] Yes, available at this link:** <https://osf.io/zsnngy>

1061 ☐ No, justification:

1062 **Do you clearly indicate in the manuscript which parts were preregistered and which**
1063 **parts were not?**

1064 **[X] Yes.** (Section 2.5 gives a concise disclosure of post-registration changes and omitted
1065 registered analyses. Table S5 distinguishes registered tests, omissions, implemented mod-
1066 ifications, and post-registration analyses.)

1067 ☐ No, justification:

1068 **Are all preregistered analyses reported in the text or linked in the supplemental mate-**
1069 **rial?**

1070 ☐ Yes.

1071 **[X] No, justification:** The registered continuous-ideology MIMIC model, complete mod-
1072 eration and simple-slope analyses, clustered correlation comparison, complete covariate
1073 set, one-tailed tests, Benjamini–Hochberg correction, and registered missing-data rule
1074 were not all implemented. Table S5 reports these omissions and the analyses used instead.

1075 **Are all deviations from the preregistration plan clearly disclosed in the manuscript**
1076 **(either in text or in a table)?**

1077 **[X] Yes.** (Section 2.5 and Table S5 disclose the changed inferential hierarchy, omitted reg-
1078 istered procedures, instrument discrepancies, and post-registration additions. TOST and
1079 its ± 0.20 SESOI are explicitly labelled exploratory.)
